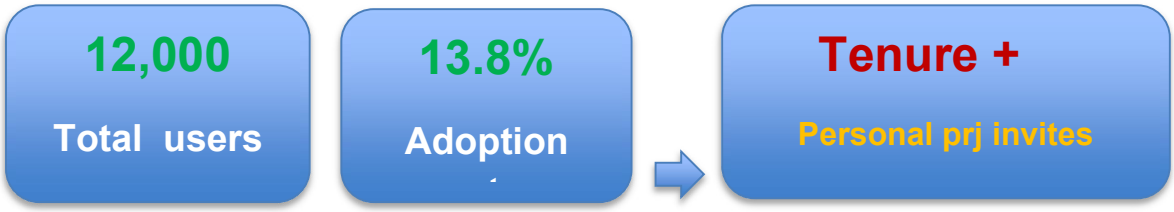
User Adoption Analysis

Relax Inc. Challenge Findings

By Irina Kim



Executive Summary

This report identifies the key predictors of user adoption for Relax Inc. We defined Adoption as any user who logged into the product on three separate days in at least one seven-day period. This strict criterion filters for users who have integrated the product into their weekly workflow.

Primary Predictor: The most significant factor in predicting adoption is User Tenure (the time between account creation and their last login).

Predictive Factors

Factor	Significance	Insight
Tenure	Very high	users who stay active beyond the first week are 85% more likely to adopt
Creation source	Medium	users invited to 'Personal Projects' show significantly lower adoption than those signing up via 'Google Auth'
Mailing List	Low	Opting into the mailing list had no statistically significant impact on adoption.

Key Adoption Metrics

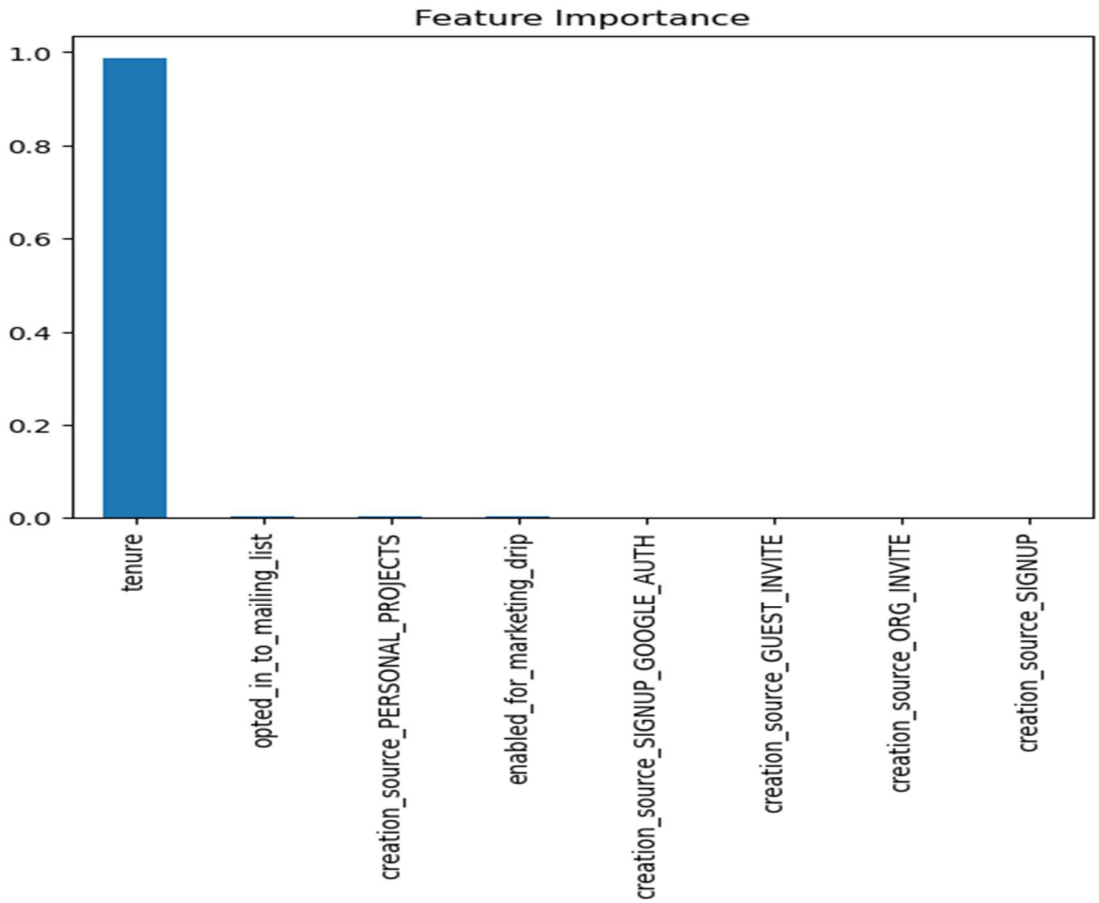
Metric	Value
Total Users Analyzed	12,000
Adopted Users	1,656
Adoption Rate	13.8%

3. Key Findings & Feature Importance

Using a Random Forest classifier to analyze user behavior and metadata, the following factors were identified as the strongest predictors of adoption:

- User Tenure: The strongest predictor. Users who remain active beyond their first week of signup are significantly more likely to adopt.
- Creation Source: Users invited to 'Personal Projects' show lower adoption rates compared to those signing up via 'Google Auth'.
- Marketing Engagement: Features like 'opted_in_to_mailing_list' had negligible impact on actual adoption.
- Organizational affiliation (org_id) also plays a secondary role, suggesting that adoption may be "contagious" within certain groups.

4. Strategic Recommendations

1. Focus on **early activation**: Since tenure is key, the product team should optimize the **first 7 days of the user experience**.


2. Optimize **Invite Flows**: Investigate the friction in 'Personal Projects' invitations to improve the conversion of invited collaborators.
